- 1 Insurance risk theory
- 2 Link to double spending
- 3 Link to blockchain mining

Cramer-Lunberg model

Insurance risk theory

The financial reserves of an insurance company over time have the following dynamic

$$R_t = z + ct - \sum_{i=1}^{N_t} U_i, \quad t \geq 0,$$

where

- $z > 0$ denotes the initial reserves
- c is the premium rate
- $(N_t)_{t \geq 0}$ is a counting process that models the claim arrival
 - Poisson process with intensity λ
- The U_i 's are the randomly sized compensations
 - non-negative, **i.i.d.**

Ruin probabilities

Insurance risk theory

Define the ruin time as

$$\tau_z = \inf\{t \geq 0; R_t < 0\}$$

and the ruin probabilities as

$$\psi(z, t) = \mathbb{P}(\tau_z < t) \text{ and } \psi(u) = \mathbb{P}(\tau_z < \infty)$$

We look for z such that

$$\mathbb{P}(\text{Ruin}) = \alpha \text{ (0.05),}$$

given that

$$c = (1 + \eta)\lambda \mathbb{E}(U),$$

with

$$\eta > 0 \text{ (net profit condition)}$$

otherwise

$$\psi(z) = 1.$$

S. Asmussen and H. Albrecher, *Ruin Probabilities*.

WORLD SCIENTIFIC, sep 2010.

Ruin probability computation

Insurance risk theory

Let

$$S_t = z - R_t, \quad t \geq 0$$

Theorem (Wald exponential martingale)

If $(S_t)_{t \geq 0}$ is a Lévy process or a random walk then

$\{\exp[\theta S_t - t\kappa(\theta)] \mid t \geq 0\}$, is a martingale,

where $\kappa(\theta) = \log \mathbb{E}(e^{\theta S_1})$.

Theorem (Representation of the ruin probability)

If $S_t \xrightarrow{\text{a.s.}} -\infty$, and there exists $\gamma > 0$ such that $\{e^{\gamma S_t} \mid t \geq 0\}$ is a martingale then

$$\mathbb{P}(\tau_z < \infty) = \frac{e^{-\gamma z}}{\mathbb{E}[e^{\gamma \xi(z)} | \tau_z < \infty]},$$

where $\xi(z) = S_{\tau_z} - z$ denotes the deficit at ruin.

Sketch of Proof

Insurance risk theory

- Because of the net profit condition $S_t = \sum_{i=1}^{N_t} U_i - ct \rightarrow -\infty$ as $t \rightarrow \infty$
- $(S_t)_{t \geq 0}$ is a Lévy process, let γ be the (unique, positive) solution to

$$\kappa(\theta) = 0 \text{ (Cramer-Lundberg equation).}$$

- $(e^{\gamma S_t})_{t \geq 0}$ is a Martingale then apply the Optional stopping theorem at τ_z .

Double spending in Satoshi's framework

Link to double spending

- The risk reserve process is $R_t = z + Y_1 + \dots + Y_t$.
- The claim surplus process is $S_t = -(Y_1 + \dots + Y_t)$.
- $\kappa(\theta) = 0$ is equivalent to

$$pe^{-\theta} + qe^{\theta} = 1.$$

$$\hookrightarrow \gamma = \log(p/q).$$

- If $p > q$ then $S(t) \rightarrow -\infty$.
- $\xi(z) = S_{\tau_z} - z = 0$ **a.s.**

Thus,

$$\mathbb{P}(\tau_z < \infty) = \left(\frac{q}{p}\right)^z.$$

Double spending with Poisson processes

Link to double spending

- Suppose that

$$N_t \sim \text{Pois}(\lambda t) \text{ and } M_t \sim \text{Pois}(\mu t)$$

such that $\lambda > \mu$.

- The risk reserve process is $R_t = z + N_t - M_t$.
- The claim surplus process is $S_t = M_t - N_t$.

Fact

The difference of two Poisson processes is not a Poisson process, However it is Lévy!

Double spending with Poisson processes

Link to double spending

- $\kappa(\theta) = 0$ is equivalent to

$$\mu e^{\theta} + \lambda e^{-\theta} - (\lambda + \mu) = 0.$$

$$\hookrightarrow \gamma = \log(\lambda/\mu).$$

- If $\lambda > \mu$ then $S_t \rightarrow -\infty$.
- $\xi(z) = S_{\tau_z} - z = 0$ **a.s.**

Thus

$$\mathbb{P}(\tau_z < \infty) = \left(\frac{\mu}{\lambda}\right)^z.$$

Double spending cost

Link to double spending

Mining cryptocurrency in PoW equipped blockchain is energy consuming

→ Operational cost for miners

Per time unit a miner pays

$$c = \pi_W \cdot W \cdot p,$$

where

- π_W is the electricity price per kWh
- W is the consumption of the network <https://cbeci.org/>
- p is the miner's hashpower

Fact

The cost of double spending is $c \cdot \tau_Z$.

Theorem (P.d.f. of the double spending time)

If $\{N_t, t \geq 0\}$ is a Poisson process then the **p.d.f.** of τ_Z is given by

$$f_{\tau_Z}(t) = \mathbb{E} \left[\frac{Z}{Z + N_t} f_{S_{N_t+Z}}(t) \right], \text{ for } t \geq 0.$$

Sketch of the proof

Link to double spending

Let's condition upon the values of N_t ,

- if $N_t = 0$ then

$$\tau_z = S_z \text{ and } f_{\tau_z|N_t=0}(t) = f_{S_z}(t)$$

- If $N_t = n$ for $n \geq 1$ then

$$\{\tau_z = t\} = \bigcup_{k=1}^n \{T_k \leq S_{z+k-1}\} \cup \{S_{n+z} = t\}$$

We have

$$\begin{aligned} f_{\tau_z|N_t=n}(t) &= \mathbb{P}(U_{1:n} \leq S_z/t, \dots, U_{n:n} \leq S_{z+n-1}/t \mid S_{n+z} = t) f_{S_{n+z}}(t) \\ &= \frac{z}{z+n} f_{S_{n+z}}(t). \end{aligned}$$

Thanks to the properties of the Abel-Gontcharov polynomials.

Dual risk model

Link to blockchain mining

A blockchain miner with hashpower share $p \in (0,1)$ that

- owns $u \geq 0$ at the beginning
- spend $c = \pi_W \cdot W \cdot p$ per time unit
- finds block at a rate $p\lambda$, where λ is the arrival rate of blocks

The miner's surplus is given by

$$R_t = u - c \cdot t + N_t \cdot b, \text{ (Dual risk model)}$$

where

- $(N_t)_{t \geq 0}$ is a Poisson process with intensity $p \cdot \lambda$
- b is the block finding reward (6.25 BTC) bitcoinhalf.com

Expected profit given not ruin

Link to blockchain mining

Fact

The steady operational cost compensated by infrequent capital gains makes mining a risky business.

Define the ruin time

$$\tau_u = \inf\{t \geq 0 ; R_t \leq 0\}$$

- Risk measure

$$\psi(u, t) = \mathbb{P}(\tau_u \leq t)$$

- Profitability measure

$$V(u, t) = \mathbb{E}(R_t \mathbb{I}_{\tau_u > t})$$

Miner's dilemma

Link to blockchain mining

Use ψ and V to compare solo mining to

- Joining a mining pool

M. Rosenfeld, "Analysis of bitcoin pooled mining reward systems," 2011.

H. Albrecher and P.-O. Goffard, "On the profitability of selfish blockchain mining under consideration of ruin," *To appear in Operations Research*, May 2021.
<https://arxiv.org/abs/2010.12577>.

Tractable formulas follow from

$$\hat{\psi}(u, t) = \mathbb{E}[\psi(u, T)] \text{ and } \hat{V}(u, t) = \mathbb{E}[V(u, T)],$$

where $T \sim \text{Exp}(t)$.

When mining solo

[Link to blockchain mining](#)

Theorem (profit and ruin when mining solo)

For any $u \geq 0$, we have

$$\hat{\psi}(u, t) = e^{\rho^* u},$$

and

$$\hat{V}(u, t) = u + (p\lambda b - c)t(1 - e^{\rho^* u}),$$

where ρ^* is the negative solution of the equation

$$-c\rho + p\lambda(e^{b\rho} - 1) = 1/t. \quad (1)$$

Lambert function

The solution ρ^* of (1) is given by

$$\rho^* = -\frac{p\lambda t + 1}{ct} - \frac{1}{b} W \left[-\frac{p\lambda b}{c} e^{-b \left(\frac{p\lambda t + 1}{ct} \right)} \right],$$

where $W(\cdot)$ denotes the Lambert function.

Sketch of the proof I

Link to blockchain mining

Recall that the time horizon is random $T \sim \text{Exp}(t)$, we condition upon what happen during the time interval $(0, h)$, with $h < u/c$ so that ruin does not occur before h . Three possibilities

- (i) $T > h$ and there is no block discovery during $(0, h)$
- (ii) $T < h$ and there is no block discovery during $(0, T)$
- (iii) There is a block discovery before time T and in the interval $(0, h)$

For the expected profit $\hat{V}(u, t)$, we get

$$\begin{aligned}\hat{V}(u, t) &= e^{-h(1/t+p\lambda)} \hat{V}(u-ch, t) + \int_0^h \frac{1}{t} e^{-s(1/t+p\lambda)} (u-cs) ds \\ &\quad + \int_0^h p\lambda e^{-s(1/t+p\lambda)} \hat{V}(u-cs+b, t) ds.\end{aligned}$$

Now we take the derivative with respect to h and set $h=0$ to obtain

$$c\hat{V}'(u, t) + \left(\frac{1}{t} + p\lambda\right) \hat{V}(u, t) - p\lambda \hat{V}(u+b, t) - \frac{u}{t} = 0, \quad (2)$$

Sketch of the proof II

Link to blockchain mining

with boundary condition

$$\hat{V}(0, t) = 0 \text{ and such that } 0 \leq \hat{V}(u, t) \leq u - ct + p\lambda t \text{ for } u > 0.$$

Equation (2) is an advanced functional differential equation, consider solutions of the form

$$\hat{V}(u, t) = Ae^{\rho u} + Bu + C, \quad u \geq 0, \quad (3)$$

where A, B, C and ρ are constants to be determined. Substituting (3) in (2) together with the boundary condition yields the system of equations

$$\begin{cases} 0 &= ct\rho + (1 + p\lambda t) - p\lambda te^{\rho b}, \\ 0 &= B(1 + tp\lambda) - p\lambda tB - 1, \\ 0 &= Bct + C(1 + tp\lambda) - p\lambda tBb - p\lambda tC, \\ 0 &= A + C. \end{cases}$$

We then have $A = -t(p\lambda b - c)$, $B = 1$, $C = t(p\lambda b - c)$ and ρ is solution of

$$c\rho + (1 + p\lambda t) - p\lambda te^{\rho b} = 0,$$

Sketch of the proof III

[Link to blockchain mining](#)

which admits one negative and one positive solution. As $A < 0$, we have to choose the negative solution $\rho^* < 0$ in order to ensure $\hat{V}(u, t) > 0$. Substituting A, B, C and ρ^* in (3) yields the result. Similarly, the ruin probability is solution to

$$c\hat{\psi}'(u, t) + (p\lambda + 1/t)\hat{\psi}(u, t) - p\lambda\hat{\psi}(u + b, t) = 0$$

with initial condition $\hat{\psi}(0, t) = 1$ and boundary condition $\lim_{u \rightarrow \infty} \hat{\psi}(u, t) = 0$.

How does a mining pool works ?

[Link to blockchain mining](#)

A set of miners $I \subset \{1, \dots, n\}$ join forces and gather a share

$$p_I = \sum_{i \in I} p_i,$$

of the total mining power.

- a pool manager coordinates
- miners prove their contribution by submitting *shares*

Definition (share)

A *share* is a partial solution to the cryptopuzzle

The pool manager sets

- the redistribution system
- the relative difficulty $q \in (0, 1)$ of finding a *share* compared to finding a block
- the pool participation fee f

Redistribution systems

Link to blockchain mining

Miners should be retributed in proportion to their contribution to the mining effort.

Proportional reward system

A *round* is the time elapsed between two block discoveries

- s_i the number of shares submitted by miner $i \in I$ during the *round*
- Each miner receives at the end of the *round*

$$(1 - f) \cdot b \cdot \frac{s_i}{\sum_{i \in I} s_i},$$

where f represents the pool manager's cut.

- The system is fair as $\frac{s_i}{\sum_{i \in I} s_i}$ should converges toward $\frac{p_i}{\sum_{i \in I} p_i}$

What's wrong with going proportional ?

Link to blockchain mining

Fact

The proportional reward system is fair but it is not incentive compatible

O. Schrijvers, J. Bonneau, D. Boneh, and T. Roughgarden, "Incentive compatibility of bitcoin mining pool reward functions," in *Financial Cryptography and Data Security*, pp. 477–498, Springer Berlin Heidelberg, 2017.

Why ?

- The durations of a round is random
 - ↳ A *share* is worth less in longer round \Rightarrow *pool hopping*
 -  M. Rosenfeld, "Analysis of bitcoin pooled mining reward systems," 2011.
 - ↳ Apply a discounting factor on the value of a *share*
 -  slush pool, "Reward system specifications," 2021.
- A miner may postpone the communication of a solution
 - ↳ She may awaits for her number of *share* to match her actual hashpower
- Absolutely no risk tranfer from miners to manager
 - ↳ f should be low

Pay-per-Share (PPS) reward system

[Link to blockchain mining](#)

The pool manager gives out

$$w = (1 - f) \cdot q \cdot b$$

for each submitted share and keep the block reward.

Miner's viewpoint

$$R_t^i = u_i - ct + M_t^i w, \quad t \geq 0.$$

where

- $(M_t^i)_{t \geq 0}$ is a Poisson process with intensity $p_i \mu = p_i \lambda / q$
- μ corresponds to the rate at which the network find *shares*

Manager's viewpoint

$$R_t^I = u_I - M_t^I w + N_t^I b, \quad t \geq 0.$$

where

- $(M_t^I)_{t \geq 0}$ is a Poisson process with intensity $p_I \mu = p_I \lambda / q$
- $(N_t^I)_{t \geq 0}$ is a Poisson process with intensity $p_I \lambda$

Pool manager at risk ?

Link to blockchain mining

For mathematical convenience we replace the deterministic reward by stochastic ones, the wealth of the pool manager becomes

$$R_t = u - \sum_{i=1}^{M_t} W_i + \sum_{j=1}^{N_t} B_j, \quad t \geq 0.$$

where

- $(M_t)_{t \geq 0}$ and $(N_t)_{t \geq 0}$ are Poisson processes with intensity $\mu^* = \mu - \lambda$ and λ
- $(W_i)_{i \geq 0}$ and $(B_j)_{j \geq 0}$ are two independent sequence of iid exponentially distributed random variables with mean w and $b^* = b - w$

Poisson process superposition

A block discovery triggers automatically a payment to the miner, specifying

- the intensity of M_t as $\mu^* = \mu - \lambda$
- the size of the upward jumps as $b^* = b - w$

allows us to isolate the downward jumps and make the Poisson processes independent.

Pool manager at risk ?

[Link to blockchain mining](#)

Theorem (Profit and ruin of the pool manager)

The ruin probability is given by

$$\hat{\psi}(u, t) = (1 - Rw)e^{-Ru}, \quad u \geq 0,$$

and the expected profit is given by

$$\hat{V}(u, t) = (1 - Rw)[w - t(\lambda b^* - \mu^* w)]e^{-Ru} + u + t(\lambda b^* - \mu^* w),$$

where R is the (unique) solution with positive real part of

$$-(t^{-1} + \lambda + \mu^*) + \lambda(1 + b^* r)^{-1} + \mu^*(1 - wr)^{-1} = 0.$$

H. Albrecher, D. Finger, and P.-O. Goffard, "Blockchain mining in pools : Analyzing the trade-off between profitability and ruin," 2021.

Sketch of the Proof I

Link to blockchain mining

We condition upon what happen during the time interval $(0, h)$. Three possibilities

- (i) $T > h$ and no jump during $(0, h)$
- (ii) $T < h$ and no jump over $(0, T)$
- (iv) An upward jump in the interval $(0, h)$
- (iii) A downward jump in the interval $(0, h)$

$$\begin{aligned}\widehat{V}(u, t) &= e^{-(\frac{1}{t} + \lambda + \mu^*)h} \widehat{V}(u, t) + \frac{1}{t} \int_0^h e^{-s/t} e^{-(\lambda + \mu^*)s} u ds \\ &+ \lambda \int_0^h e^{-\lambda s} e^{-(1/t + \mu^*)s} \int_0^\infty \widehat{V}(u+x, t) dF_B(x) ds \\ &+ \mu^* \int_0^h e^{-\mu^* s} e^{-(1/t + \lambda)s} \int_0^u \widehat{V}(u-y, t) dF_W(y) ds.\end{aligned}$$

Differentiating with respect to h and letting $h \rightarrow 0$ yields the following integral equation

$$\lambda \int_0^\infty \widehat{V}(u+x, t) dF_B(x) - (\lambda + \mu^* + 1/t) \widehat{V}(u, t) + \mu^* \int_0^u \widehat{V}(u-y, t) dF_W(y) + u/t = 0, \quad u \geq 0, \quad (4)$$

with boundary conditions $\widehat{V}(u, t) = 0$ for all $u < 0$ and $0 \leq \widehat{V}(u, t) \leq u + (\lambda b^* - \mu^* w)$. Let us plug in the ansatz

$$C e^{-ru} + d_1 u + d_0$$

Sketch of the Proof II

Link to blockchain mining

- Comparing the terms in e^{-ru} gives an equation for r

$$-(t^{-1} + \lambda + \mu^*) + \lambda(1 + b^*r)^{-1} + \mu^*(1 - wr)^{-1} = 0$$

of which only the positive solution $R > 0$ is valid due to the boundary conditions.

- Comparing the terms in u yields $d_1 = 1$
- Comparing the terms in 1 yields

$$d_0 = t(\lambda b^* - \mu^* w)$$

- Comparing the terms in $e^{-u/w}$

$$C = (1 - R w)[w - t(\lambda b^* - \mu^* w)]$$

Markov model

Link to blockchain mining

- Let $(Z_n)_{n \geq 0}$ be the number of blocks in the selfish miner's buffer with state space $\{0, 0^*, 1\}$.
- The transition graph is given by

- The reward collecting process is also Markovian as

$$f[Z_{n-1}, \xi_n, \zeta_n] = \begin{cases} 0, & \text{if } Z_{n-1} = 0, \\ 0, & \text{if } Z_{n-1} = 1 \text{ \& } \xi_n = 0, \\ 2, & \text{if } Z_{n-1} = 1 \text{ \& } \xi_n = 1, \\ 0, & \text{if } Z_{n-1} = 0^* \text{ \& } \xi_n = 0 \text{ \& } \zeta_n = 0, \\ 1, & \text{if } Z_{n-1} = 0^* \text{ \& } \xi_n = 0 \text{ \& } \zeta_n = 1, \\ 2, & \text{if } Z_{n-1} = 0^* \text{ \& } \xi_n = 1. \end{cases}$$

where $\xi_n \sim \text{Ber}(p)$ and $\zeta_n \sim \text{Ber}(q)$

Wealth of a selfish miner

Link to blockchain mining

The wealth process of a selfish miner is given by

$$R_t = u - c \cdot t + b \cdot \sum_{n=1}^{N_t} f(Z_k, \xi_n, \zeta_n).$$

where N_t is a Poisson process with intensity λ that corresponds to the arrival of blocks in the blockchain.

- The net profit condition reads as

$$\frac{b}{t} \mathbb{E} \left[\sum_{n=1}^{N_t} f(Z_k, \xi_n, \zeta_n) \right] > c$$

- Once stationarity is reached we have

$$\mathbb{P}(Z_\infty = 0) = \frac{1}{1+2p-p^2}, \quad \mathbb{P}(Z_\infty = 1) = \frac{p}{1+2p-p^2}, \quad \text{and} \quad \mathbb{P}(Z_\infty = 0^*) = \frac{p(1-p)}{1+2p-p^2},$$

and the net profit condition correspondingly reads

$$b\lambda \frac{qp(1-p)^2 + 4p^2 - 2p^3}{1+2p-p^2} - c > 0.$$

Expected profit of a selfish miner

Link to blockchain mining

Define

$$\hat{\psi}_z(u, t) \equiv \mathbb{E}(\psi_z(u, T)) = \mathbb{E}(\psi(u, T) | Z_0 = z) \text{ and } \hat{V}_z(u, t) \equiv \mathbb{E}(V_z(u, T)) = \mathbb{E}(R_T \mathbb{1}_{\tau_u > T} | Z_0 = z)$$

Theorem

For any $u \geq 0$, the ruin probability and expected profit of a selfish miner are given by

$$\hat{\psi}_0(u, t) = C_1 e^{\rho_1 u} + e^{\rho_2 u} [C_2 \cos(\rho_3 u) + C_3 \sin(\rho_3 u)],$$

and

$$\hat{V}_0(u, t) = A_1 e^{\rho_1 u} + e^{\rho_2 u} [A_2 \cos(\rho_3 u) + A_3 \sin(\rho_3 u)] + u + C,$$

Conclusion and perspectives

Link to blockchain mining

- Selfish mining entails a waste of resources for everybody
- Including a difficulty adjustment can make it strategic
- Possible extensions

- 1 Consider stochastic jumps
- 2 Consider the actual selfish mining strategy
- 3 Consider generalization of the selfish mining strategy

A. Sapirshtein, Y. Sompolinsky, and A. Zohar, "Optimal selfish mining strategies in bitcoin," in *Financial Cryptography and Data Security*, pp. 515–532, Springer Berlin Heidelberg, 2017.

→ Stochastic control problem !

- 4 Better understanding of the connectivity parameter q
