## Consensus protocol

#### Definition

Algorithm to allows the full nodes to agree on a common data history

It must rely on the scarce resources of the network

- bandwidth
- computational power
- storage (disk space)

# Types of consensus protocols

## 1 Voting based

L. Lamport, R. Shostak, and M. Pease, "The byzantine generals problem," *ACM Transactions on Programming Languages and Systems*, pp. 382–401, July 1982.

#### 2 Leader based

- Proof-of-Work (computational power)
- Proof-of-Capacity and Proof-of-Spacetime (storage)
- Proof-of-Interaction (bandwidth)
- Proof-of-Stake (tokens)

## Conflict resolution in blockchain

#### Fork

A fork arises when there is a disagreement between the nodes resulting in several branches in the blockchain.

#### **LCR**

The Longest Chain Rule states that if there exist several branches of the blockchain then the longest should be trusted.

#### In practice

- A branch can be considered legitimate if it is  $k \in \mathbb{N}$  blocks ahead of its pursuers.
- Fork can be avoided when

block appending time > propagation delay

## Two generals problem

Two nodes who must agree are communicating through an unreliable link.

Analogy with two generals besieging a city

The generals exchange messages through enemy territory

G1

"I will attack tomorrow at dawn, if you confirm"

G2

"I will follow your lead, if you confirm"

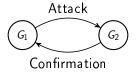

Figure – Message and confirmation loop

# Byzantine General problem

n generals must agree on a common battle plan, to either

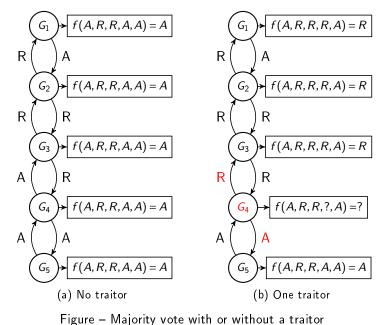

- Attack (A)
- Retreat (R)

#### Problem

There are m < n traitors among the generals

- 1 message m(i,j) is sent to general j by general i
- **2** Consensus is reached as general j applies

$$f\big(\{m\big(i,j\big);\ i=1,\ldots,n\}\big) = \begin{cases} A, & \text{if } \sum_{i=1}^n \mathbb{I}_{m\big(i,j\big)=A} > n/2, \\ R, & \text{else.} \end{cases}$$

## **Commanders and Lieutenants**

One general is the commander while the others are the lieutenants

#### Objective

Design an algorithm so that the following conditions are met:

- C1 All the loyal lieutenants obey the same order
- C2 If the commanding general is loyal, then every loyal lieutenants obey the order he sends

## Byzantine Fault Tolerance Theorem (Lamport et al.)

There are no solution to the Byzantine General problem for n < 3m+1 generals, where m is the number of traitors.

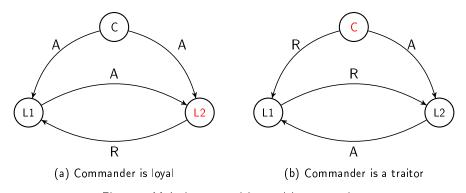

Figure - Majority vote with or without a traitor

## **Algorithm** The Oral message algorithm OM(m)

```
if m=0 then:
   for i = 1 \rightarrow n-1 do
       Commander sends v_i = v to lieutenant i
       Lieutenant i set their value to v
   end for
end if
if m > 0 then:
   for i = 1 \rightarrow n-1 do
       Commander sends v_i to lieutenant i
       Lieutenant i uses OM(m-1) to communicate v_i to the n-2 lieute-
nants
   end for
   for i = 1 \rightarrow n-1 do
       Lieutenant i set their value to f(v_1,...,v_{n-1})
   end for
end if
```

# n=4 and m=1: Step 1

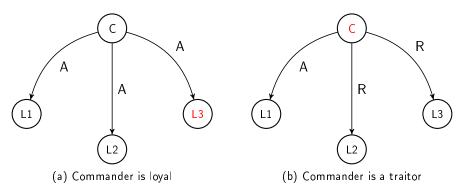

Figure – Illustration of the OM(m) algorithm in the case where n = 4 and m = 1.

# n = 4 and m = 1 : Step 2

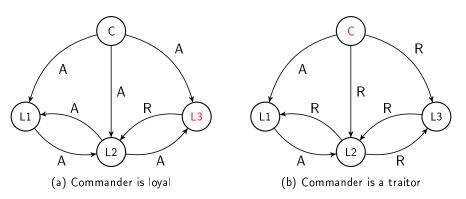

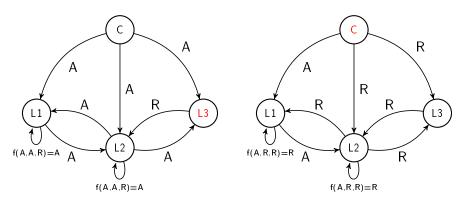

Figure – Illustration of the OM(m) algorithm in the case where n = 4 and m = 1.

## n=4 and m=1: Step 3

(a) Commander is loyal, C1 and C2

(b) Commander is a traitor, C1

Figure – Illustration of the OM(m) algorithm in the case where n = 4 and m = 1.

## The problem with majority vote

The OM algorithm requires to send  $n^{m+1}$ 

- ↑ Communication overhead
- ♠ Denial of service

#### Solution

Leader based protocols!

## Proof-of-Work

### Objective

Elect a leader based on computational effort to append the next block.

## What's inside a block?

#### A block consists of

- a header
- a list of "transactions" that represents the information recorded through the blockchain.

#### The header usually includes

- the date and time of creation of the block,
- the block height which is the index inside the blockchain,
- the hash of the block
- the hash of the previous block.

#### Question

What is the hash of a block?

# Cryptographic Hash function

A function that maps data of arbitratry size (message) to a bit array of fixed size (hash value)

$$h: \{0,1\}^* \mapsto \{0,1\}^d$$
.

A good hash function is

- deterministic
- quick to compute
- One way
  - $\hookrightarrow$  For a given hash value  $\overline{h}$  it is hard to find a message m such that

$$h(m) = \overline{h}$$

- Colision resistant
  - $\rightarrow$  Impossible to find  $m_1$  and  $m_2$  such that

$$h(m_1) = h(m_2)$$

Chaotic

$$m_1 \approx m_2 \Rightarrow h(m_1) \neq h(m_2)$$

## SHA-256

The SHA-256 function which converts any message into a hash value of 256 bits.

#### Example

The hexadecimal digest of the message

Blockastics is fantastic

is

60 a 147 c 285 68 d c 925 c 347 b c e 20 c 910 e f 90 f 3774 e 250 1 a c 63344 f 3411 b 6a6 b f 790 f 3774 e 250 f 3774

# Mining a block

```
Block Hash: 1fc23a429aa5aaf04d17e9057e03371f59ac8823b1441798940837fa2e318aaa
Block Height: 0
Time:2022-02-25 12:42:04.560217
Nonce:0
Block data: [{'sender': 'Coinbase', 'recipient': 'Satoshi', 'amount': 100, 'fee': 0}, {'sender': 'Satoshi', 'recipient': 'Pierre-O', 'amount': 5, 'fee': 2}]
Previous block hash: 0
Mined: False
```

Figure - A block that has not been mined yet.

# Mining a block

The maximum value for a 256 bits number is

$$T_{\text{max}} = 2^{256} - 1 \approx 1.16e^{77}$$
.

Mining consists in drawing at random a nonce

Nonce 
$$\sim \text{Unif}(\{0,...,2^{32}-1\}),$$

until

$$h(Nonce|Block info) < T$$
,

where T is referred to as the target.

Difficulty of the cryptopuzzle

$$D = \frac{T_{\text{max}}}{T}.$$

# Mining a block

If we set the difficulty to  $D=2^4$  then the hexadecimal digest must start with at least 1 leading 0

```
Block Hash: 0869032ad6b3e5b86a53f9dded5f7b09ab93b24cd5a79c1d8c81b0b3e748d226
Block Height: 0
Time:2022-02-25 13:41:48.039980
Nonce:2931734429
Block data: [{'sender': 'Coinbase', 'recipient': 'Satoshi', 'amount': 100, 'fee': 0}, {'sender': 'Satoshi', 'recipient': 'Pierre-O', 'amount': 5, 'fee': 2}]
Previous block hash: 0
Mined: True
```

Figure – A mined block with a hash value having on leading zero.

The number of trial is geometrically distributed

- Exponential inter-block times
- Lenght of the blockchain = Poisson process

## Bitcoin protocol

- One block every 10 minutes on average
- Depends on the hashrate of the network
- Difficulty adjustment every 2,016 blocks (≈ two weeks)
- Reward halving every 210,000 blocks

Check out https://www.bitcoinblockhalf.com/

# Mining equipments

#### How it started

CPU, GPU

#### How it is going

- Application Specific Integrated Chip (ASIC)
  - Increase of the network electricity consumption
    https://digiconomist.net/bitcoin-energy-consumption
  - E-Waste
  - Centralization issue https://www.bitmain.com/
    - Mining pool ranking at https://btc.com/
    - Mining equipment profitability at https://v3.antpool.com/minerIncomeRank

## **Proof of Stake**

PoW is slow and ressource consuming. Let  $\{1,...,N\}$  be a set of miners and  $\{\pi_1,...,\pi_N\}$  be their share of cryptocoins.

#### PoS

1 Node  $i \in \{1,...,N\}$  is selected with probability  $\pi_i$  to append the next block

Nodes are chosen according to what they own.

- Nothing at stake problem
- Rich gets richer?
- https://www.peercoin.net/

F. Saleh, "Blockchain without waste: Proof-of-stake," *The Review of Financial Studies*, vol. 34, pp. 1156–1190, jul 2020.

# Using storage

- Proof-Of-Capacity:
  - 1 Store solution to the PoW cryptopuzzle in a large file
  - 2 Read through the cache for an acceptable solution
- Proof-of-Spacetime
  - 1 Deliver proof of storing some data during some time
  - 2 Probability of being selected proportional to the amount of data stored times duration of the storage
  - 3 https://filecoin.io/

# Using bandwidth

#### Proof-of-Interaction

- The node receives a list of node they must get in touch with
- The first one who is able to complete the task gets a reward and share it with the responding nodes
